Introduction

This document describes the operation, verification, and troubleshooting procedures for High Availability (HA) on Firepower Threat Defense (FTD).

Prerequisites

Requirements

Cisco recommends knowledge of these topics:

- FTD and ASA platforms
- Packet captures on FTD appliances

It is highly recommended that the Firepower Configuration Guide [Configure FTD High Availability on Firepower Appliances](#) is read to better comprehend the concepts described in this document.

Components Used

The information in this document is based on these software and hardware versions:

- Cisco FTD
- Cisco Firepower Management Center (FMC)

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

Background Information

The information and the examples are based on FTD, but most of the concepts are also fully applicable to Adaptive Security Appliance (ASA).

An FTD supports two main management modes:

- Off-box via FMC - also known as remote management
- On-box via Firepower Device Manager (FDM) - also known as local management

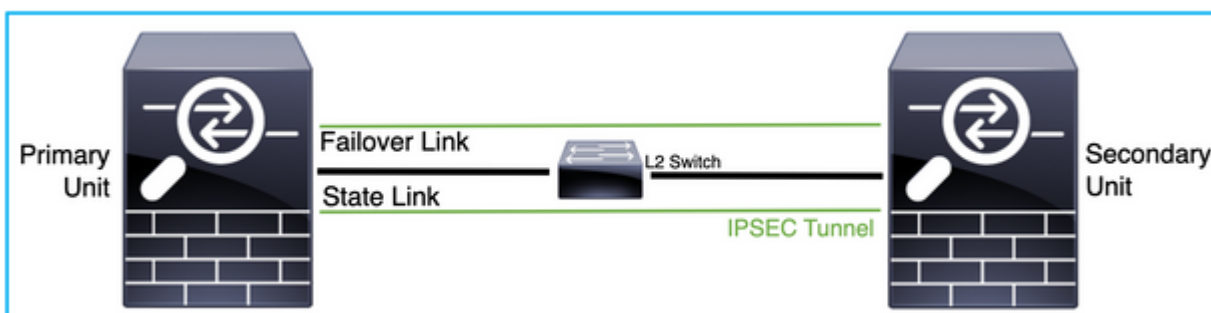

Note: FTD managed via FDM can be added in High Availability from Firepower version code v6.3.0 onwards.

Design Options

From a design point of view of the FTD, it can be directly connected, as shown in this image:

Or, it can be connected via Layer 2 (L2) switch, as shown in this image:

HA Terminology

Active	The active ASA receives all traffic flows and filters all network traffic. The configuration changes are made on the active ASA.
HA Link	<p>The two units in a failover pair constantly communicate over a failover link to determine the operating status of each unit and to synchronize configuration changes. The information shared over the link is:</p> <ul style="list-style-type: none"> • The unit state (active or standby) • Hello messages (keep-alive) • Network link status • MAC address exchange • Configuration replication and synchronization
Primary	This is the unit that is usually configured first when you create an HA. The significance of this is that if both the devices of an ASA HA were to come up together at the exact same instant, the primary assumes the active role.
Secondary	This is the unit that is usually configured second when you create an HA. The significance of this is that, if both the devices of an ASA HA were to come up together at the exact same instant, the secondary assumes the standby role.
Standby	The standby ASA does not handle any live traffic, it syncs the connections and the configuration from the active device, and takes up the active role in case of a failover.
State Link	The active unit uses the state link to pass connection state information to the standby device. Therefore, the standby unit can maintain certain types of connections and it does not affect you. This information helps the standby unit to maintain the connections that exist when a failover occurs. NB: When you use the same link for failover and stateful failover, you conserve interfaces the best. However, you must consider a dedicated interface for the state link and failover link, if you have a large configuration and a high traffic network. We recommend that the bandwidth of the stateful failover link must match the largest bandwidth of the data interfaces on the device.

HA States

Active	The device currently handles the live traffic on the network, and all the configuration changes that need to be done are to be performed on this device.
App Sync	The device in this state synchronizes the configuration from the active device.

Bulk Sync	The device in this state synchronizes the configuration from the active device.
Disabled	The failover on the unit has been disabled (command: no failover).
Negotiation	The device checks for the availability of the active device and takes the active role if the active device is not found to be standby ready.
Standby Ready	The device currently does not handle traffic but takes on the active role if the active device shows any health check issues.
Sync Configuration	The configuration is replicated from the active device to the standby device.
Cold Standby	The device takes over as active on failover but does not replicate the connection events.

HA State Flow Diagram

Primary (without any connected peer):

Secondary (with an Active connected peer):

UI Verification

Firepower Management Center Managed FTD HA

The FTD HA state can be checked from FMC UI when you navigate to **Device > Device Management**, as shown in this image:

Firepower Management Center
Devices / Device Management

Scenarios

If the peer unit fails to join the HA group or fails while you deploy changes from the active unit, log into the failed unit, navigate to the High Availability page, and click the Failover History link.

APP-SYNC Failure

If the show failover history output indicates an App Sync failure, then there was a problem at the time of the HA validation phase, where the system checks that the units can function correctly as a high availability group.

The message "All validation passed" when the From State is App Sync appears, and the node moves to the Standby Ready state.

Any validation failure transitions the peer to the Disabled (Failed) state. Resolve the problems to make the peers function as a high availability group again.

Note that if you fix an App Sync error and make changes to the active unit, you must deploy them and then resume HA for the peer node to join.

The messages indicate failures, with an explanation of how you can resolve the issues. These errors can happen on node join and on each subsequent deployment.

At the time of a node join, the system performs a check against the last deployed configuration on the active unit.

Standby Node Fails to Join HA with "CD App Sync error is App Config Apply Failed"

On the Standby FTD command line, `/ngfw/var/log/action_queue.log` must have the reason for configuration failure.

Remediation: On identification of the configuration error, post-making required changes, HA can be resumed.

See Cisco bug ID [CSCvu15611](#).

Standby Node Fails to Join HA with "HA state progression failed due to APP SYNC timeout"

On the Standby FTD command line, `/ngfw/var/log/ngfwmanager.log` must have the reason for the app-sync timeout.

At this stage, policy deployments also fail because the active unit thinks app sync is still in progress.

Policy deployment throws the error - "since newNode join/AppSync process is in progress, Configuration Changes are not allowed, and hence rejects the deployment request. Please retry deployment after some time"

Remediation: Sometimes, when you resume high availability on the Standby node, it can resolve the issue.

App Sync Disabled

HA state progression failed due to APP SYNC timeout

=====

Standby Node Fails to Join HA with "CD App Sync error is Failed to apply SSP config on standby"

On the Standby FTD command line, `/ngfw/var/log/ngfwmanager.log` must have the exact reason for the failure.

Remediation: Sometimes, when you resume high availability on the Standby node, it can resolve the issue.

See Cisco bug ID [CSCvy04965](https://tools.cisco.com/bugcenter/bug/?bugID=CSCvy04965)

=====

Health Check Failure

"HELLO not heard from mate" means the mate is offline or the failover link does not communicate the HELLO keepalive messages.

Try to log in to the other device, if SSH does not work, get the console access and check if the device is operational or offline.

If operational, identify the cause of the failure with the command, **show failover state**.

If not operational, try a graceful reboot and check if you see any boot logs on the console, otherwise, the device can be considered hardware faulty.

Snort Down or Disk Failure

If the FTD gives this error, "Detect Inspection engine failure due to disk failure", there are 2 possibilities.

The Detection Engine (SNORT Instance) is Down

This can be validated with the command on the Linux side, **pmtool status | grep -i de**,

Remediation: If any of the instances is down, check for **/ngfw/var/log/messages** and identify the cause.

The Device Shows High Disk Utilization

This can be validated with the command on the Linux side, **df -Th**.

Remediation: Identify the directory which consumes most of the disk and contact TAC to delete the unwanted files.

Service Card Failure

Such issues are generally reported because of Firepower module failure on ASA 5500-X devices. Please check the sanity of the module via **show module sfr details**.

Remediation: Collect ASA Syslog around the time of the failure, and these can contain details like control or data plane failure.

That can be due to various reasons in the SFR module. It is recommended to open TAC to find the root cause of this issue on the IPS.
